## Abstract

Let  $P$  be a simple polygon with  $n$  vertices. The geodesic center of  $P$  is the point inside  $P$  that minimizes the geodesic distance to its farthest neighbor. The best known algorithm to compute the geodesic center of  $P$  runs in  $O(n \log n)$  time and was presented in 1989. Since then, improving this running time has been a longstanding open problem. In this paper, we show how to compute the geodesic center of  $P$  in  $O(n \log^* n)$  time.

## 1 Outline

Let  $P$  be a simple polygon with  $n$  vertices. Given two points  $x, y \in P$ , let  $\pi(x, y)$  denote shortest path contained in  $P$  with endpoints  $x$  and  $y$ , i.e.,  $\pi(x, y)$  is the *geodesic path* connecting  $x$  with  $y$ . Notice that the straight-line segment connecting  $x$  with  $y$  is contained in  $P$ , then  $\pi(x, y)$  is a straight-line segment. Otherwise, it is a polygonal chain containing only reflex vertices of  $P$  other than its endpoints. The *geodesic distance* between  $x$  and  $y$ , denoted by  $|\pi(x, y)|$ , is the euclidean length of the path  $\pi(x, y)$ , i.e., the sum of the lengths of each segment in this path. Throughout this paper, when referring to the distance between two points in  $P$ , we refer to the geodesic distance between them.

Given a point  $x \in P$ , let  $f_P(x)$  (or simply  $f(x)$  when the context is clear) denote the vertex of  $P$  that is (geodesically) farthest from  $x$  (if two or more vertices are at the same distance from  $x$ , we choose one of them arbitrarily).

Let  $F_P(x) = |\pi(x, f(x))|$ , i.e.,  $F_P(x)$  is the distance from  $x$  to its farthest neighbor in  $P$ . Another way to think of the function  $F_P(x)$  is as the upper envelope of all the (geodesic) distance functions from  $x$  to the vertices of  $P$ . This is related with the farthest-point geodesic Voronoi diagram (FGV) of the vertices of  $P$ . The *Voronoi cell* of a vertex  $v$  of  $P$  is the set of points  $R(v) = \{x \in P : F_P(x) = |\pi(x, v)|\}$ .

In this paper, we represent the function  $F_P(x)$  using a set of constant complexity distance functions defined on triangles contained in  $P$  in such a way that the union of these triangles covers  $P$ . Moreover, the upper envelope of these functions coincides with  $F_P(x)$ . Then, we proceed to prune and search for the geodesic center of  $P$  by restricting our search to a sub-polygon of  $P$  and the triangles that cover this sub-polygon. By pruning a constant fraction of these triangles on each iteration, we are able to obtain a near-linear time algorithm to compute the geodesic center of  $P$ . The bottleneck of this algorithm comes from computing the set of triangles that covers  $P$  and their respective distance functions.

## 2 Hourglasses and Funnels

In this section, we provide introduce the main tools that are going to be used by the algorithm. Some of the result presented in this section have been shown before in different papers. For most of them, we present proof sketches.

### 2.1 Hourglasses

Given two points  $x$  and  $y$  on  $\partial P$ , let  $\partial P(x, y)$  be the polygonal chain that starts at  $x$  and follows the boundary of  $P$  clockwise until reaching  $y$ .

Let  $C = (p_0, p_1, \dots, p_k)$  be a polygonal chain contained in  $\partial P$  sorted in clockwise order. The *hourglass* of  $C$ , denoted by  $H_C$ , is the simple polygon contained in  $P$  bounded by  $C$ ,  $\pi(p_k, f(p_0))$ ,  $\partial P(f(p_0), f(p_k))$  and  $\pi(f(p_k), p_0)$ ; see Figure ?? . We call  $C$  and  $\partial P(f(a), f(b))$  the *top* and *bottom* chains of  $H_C$ , respectively, while  $\pi(p_k, f(p_0))$  and  $\pi(f(p_k), p_0)$  are referred to as the *walls* of  $H_C$ .

We say that the hourglass  $H_C$  is *open* if its walls are vertex disjoint. We say  $C$  is a *transition chain* if  $f(p_0) \neq f(p_k)$ . In particular, an edge  $ab$  of  $\partial P$  is a *transition edge* if  $f(a) \neq f(b)$ .

► **Lemma 1.** [Rephrase of Lemma 3.1.3 of [2]] *If  $C$  is a transition chain of  $\partial P$ , then the hourglass  $H_C$  is an open hourglass.*

Note that we have at most  $n$  transition edges, as the FGV of the vertices of  $P$  restricted to  $\partial P$  partitions the boundary into at most  $n$  disjoint connected components [2].

Given a transition chain  $C$  of  $\partial P$ , we say that the hourglass  $H_C$  is the *transition hourglass* of  $C$ . By Lemma 1, each transition hourglass is open.

The following results are similar or have already been proved by Suri [12] and Aronov et al. [2]. We provide a sketch of the proof of some of them for completeness.

The following lemma is depicted in Figure ?? and is a direct consequence of the Ordering Lemma proved by Aronov et al. [2, Corollary 2.7.4].

► **Lemma 2.** *Let  $C_1, C_2, C_3$  be three edge disjoint transition chains of  $\partial P$  that appear in this order when traversing clockwise the boundary of  $P$ . Then, the bottom chains of  $H_{C_1}, H_{C_2}$  and  $H_{C_3}$  are also edge disjoint and appear in this order when traversing clockwise the boundary of  $P$ .*

► **Lemma 3.** [Rephrase of Lemma 3.4.3 of [2]] *Let  $C_1, \dots, C_r$  be a set of edge disjoint transition chains of  $\partial P$  that appear in this order when traversing clockwise the boundary of  $P$ . Then each chord of  $P$  appears in  $O(1)$  hourglasses among  $H_{C_1}, \dots, H_{C_r}$ .*

**Proof.** Assume for a contradiction that there is an edge  $st$  that appears in the left wall of three hourglasses  $H_{C_i}, H_{C_j}$  and  $H_{C_k}$  such that  $1 \leq i < j < k \leq r$ .

Because  $C_i, C_j$  and  $C_k$  are edge disjoint, their bottom chains are also edge disjoint by Lemma 2. Therefore,  $st$  must be a vertex on the walls of these hourglasses. Assume that  $s$  is visited before  $t$  when going from the top to the bottom chain along the walls of these hourglasses. Let  $\pi(s_i, t_i)$  be the wall of  $S_i$  that passes through  $st$  such that  $s_i$  and  $t_i$  lie in the top and bottom chains of  $H_{C_i}$ , respectively. Define  $\pi(s_k, t_k)$  analogously.

Because  $C_j$  lies in between  $C_i$  and  $C_k$ , Lemma 2 implies that the bottom chain of  $C_j$  appears between the bottom chains of  $C_i$  and  $C_k$ . Therefore,  $C_j$  lie between  $s_i$  and  $s_k$  and the bottom chain of  $H_{C_j}$  lies between  $t_i$  and  $t_k$ . That is, for each  $x \in C_j$  and each  $y$  in the bottom chain of  $H_{C_j}$ , the geodesic path  $\pi(x, y)$  is “sandwiched” by the paths  $\pi(s_i, t_i)$  and

$\pi(s_k, t_k)$ . Thus,  $\pi(x, y)$  contains  $st$ . However, this implies that the hourglass  $H_{C_j}$  is not open—a contradiction that comes from assuming that  $st$  lies in the wall of three hourglasses, when this wall is traversed from the top chain to the bottom chain. Analogous arguments can be used to bound the total number of walls that contain the edge  $st$  (when traversed in any direction) to  $O(1)$ . ◀

► **Lemma 4.** [Rephrase of Lemma 4 of [12]] *Let  $C$  be a transition chain and let  $T$  and  $B$  be the top and bottom chains of  $H_C$ . Let  $x, y$  be two vertices such that  $\pi(x, y)$  separates  $T$  from  $B$ . If  $T_x$  and  $T_y$  are the shortest path trees of  $x$  and  $y$  in  $P$ , then for each  $u \in T$  and each  $v \in B$ , all edges of  $\pi(u, v)$ , except perhaps one, belong to  $T_x \cup T_y$ .*

► **Lemma 5.** *Let  $C_1, \dots, C_k$  be a set disjoint transition chains of  $\partial P$ . Then*

$$\sum_{i=1}^k |H_{C_i}| = O(n).$$

**Proof.** We claim that then number of chords used by these hourglasses is  $O(n)$ . If this claim is true, then by Lemma 3 we know that no edge is used more than a constant number of times yielding our result.

We construct  $O(1)$  split chains  $\gamma_1, \dots, \gamma_t$  such that for each  $1 \leq i \leq k$ , there is a split chain  $\gamma_j$  that separates the top and bottom chain of  $H_{C_i}$  (to see how to construct this chains see Lemma 2.7.5 of [2]). For each  $1 \leq j \leq t$ , let

$$\mathcal{H}^j = \{H_{C_i} : \text{the top and bottom chain of } H_{C_i} \text{ are separated by } \gamma_j\}.$$

Since the complexity of the shortest path trees of the endpoints of  $\gamma_j$  is  $O(n)$ , and from the fact that the chains  $C_1, \dots, C_k$  are disjoint, Lemma 4 implies that the total number of edges in all the hourglasses of  $\mathcal{H}^j$  is  $O(n)$ . Moreover, because each of these edges appears in  $O(1)$  hourglasses among  $C_1, \dots, C_k$ , we conclude that

$$\sum_{H \in \mathcal{H}^j} |H| = O(n).$$

Since we have only  $O(1)$  split chains, our result follows. ◀

## 2.2 Funnels

Let  $C = (p_0, \dots, p_k)$  be a chain of the boundary of  $P$  and let  $v$  be a vertex of  $P$  not in  $C$ . The *funnel* of  $v$  to  $C$ , denoted by  $S_v(C)$ , is the simple polygon bounded by  $C$ ,  $\pi p_k v$  and  $\pi v p_0$ ; see Figure ???. Note that the paths  $\pi v p_k$  and  $\pi v p_0$  may coincide for a while before splitting into disjoint chains. The last vertex in which they coincide is the *apex* of the funnel. See Lee and Preparata [6] or Guibas et al. [3] for more details on funnels.

A subset  $R \subset P$  is *geodesically convex* if for every  $x, y \in R$ , the path  $\pi(x, y)$  is contained in  $R$ . This funnel  $S_v(C)$  is also known as the geodesic convex hull of  $C$  and  $v$ , i.e., the minimum geodesically convex set that contains  $v$  and  $C$ .

Given two points  $x, y \in P$ , the (geodesic) *bisector* of  $x$  and  $y$  is the set of points contained in  $P$  that are equidistant from  $x$  and  $y$ . This bisector is a curve, contained in  $P$ , that consists of circular arcs and hyperbolic arcs. Moreover, this curve intersects  $\partial P$  only at its endpoints [1, Lemma 3.22].

► **Lemma 6.** *Let  $v$  be a vertex of  $P$  and let  $C$  be a transition chain such that  $C$  contains  $R(v) \cap \partial P$ . Then,  $R(v)$  is contained in the funnel  $S_v(C)$*

**Proof.** Let  $a$  and  $b$  be the endpoints of  $C$  and assume that  $a, b, f(a)$  and  $f(b)$  appear in this order in a clockwise traversal of  $\partial P$ . Because  $R(v) \cap \partial P \subset C$ , we know that  $v$  lies between  $f(a)$  and  $f(b)$ .

Let  $\alpha$  (resp.  $\beta$ ) be the bisector of  $v$  and  $f(a)$  (resp.  $f(b)$ ). Let  $h_a$  (resp.  $h_b$ ) be the set of points of  $P$  that are farther from  $v$  than from  $f(a)$  (resp.  $f(b)$ ). Note that  $\alpha$  is the boundary of  $h_a$  while  $\beta$  bounds  $h_b$ .

By definition, we know that  $R(v) \subseteq h_a \cap h_b$ . Therefore, it suffices to show that  $h_a \cap h_b \subset S_v(C)$ . Assume for a contradiction that there is a point of  $h_a \cap h_b$  lying outside of  $S_v(C)$ . By continuity, there is a point  $w$  lying in the intersection of their boundaries. Without loss of generality, assume that  $w$  lies in  $\beta \cap \pi(v, b)$ , the case where  $w$  lies in  $\alpha \cap \pi(v, a)$  is analogous.

Since  $w \in \beta$ , we know that  $|\pi(w, v)| = |\pi(w, f(b))|$ . By the triangle inequality and since  $w$  cannot be a vertex of  $P$  as  $w$  intersects  $\partial P$  only at its endpoints, we get that

$$|\pi(b, f(b))| < |\pi(b, w)| + |\pi(w, f(b))| = |\pi(b, w)| + |\pi(w, v)| = |\pi(b, v)|.$$

Which implies that  $b$  is farther from  $v$  than from  $f(b)$ —a contradiction that comes from assuming that  $h_a \cap h_b$  is not contained in  $S_v(C)$ .  $\blacktriangleleft$

### 3 Decomposing the boundary

Using a result from Hershberger and Suri [5], in  $O(n)$  time we can compute the farthest neighbor of each vertex of  $P$ . We then mark the vertices of  $P$  that are farthest neighbors of at least one vertex of  $P$ . Let  $M$  denote the set of marked vertices of  $P$  which can be computed in  $O(n)$  time. In other words,  $M$  contains vertices that are guaranteed to have a non-empty Voronoi cell in the FGV of the vertices of  $P$ .

Given a vertex  $v$  of  $P$ , the vertices of  $P$  that are farthest from  $v$  than from any other vertex appear contiguously along  $\partial P$  [2]. Therefore, after computing all this farthest neighbors, we effectively split the boundary into subchains, each associated with a different vertex of  $M$ ; see Figure ??.

Let  $a$  and  $b$  be the endpoints of an edge of  $\partial P$  and assume that  $a$  appears before  $b$  in the clockwise order along  $\partial P$ . Recall that we have computed  $f(a)$  and  $f(b)$  in the previous step and note that  $f(a)$  appears also before  $f(b)$  along this clockwise order (if  $f(a) \neq f(b)$ ). For every vertex  $v$  that lies between  $f(a)$  and  $f(b)$  in this clockwise order, we know that there is no vertex  $u$  of  $P$  such that  $f(u) = v$ . As proved by Aronov et al. [2, Corollary 2.7.4], we know that if there is a point  $x$  on  $\partial P$  such that  $v = f(x)$ , then  $x$  has to lie on the open segment  $(a, b)$ . In other words, the Voronoi cell  $R(v)$  restricted to  $\partial P$  is contained in  $(a, b)$ .

### 4 Building hourglasses

Let  $E$  be the set of transition edges of  $\partial P$ . We would like to construct the corresponding hourglass of each transition edges of  $E$ . By Lemma 5  $\sum_{ab \in E} |H_{ab}| = O(n)$ . Therefore, an output sensitive algorithm would be enough for this task. However, we have no knowledge of the existence of such an algorithm. The algorithm proposed in this section achieves this task at the expense of adding a  $O(\log^* n)$  factor to the running time.

To construct these hourglasses, we use the shortest-path data structure of Guibas and Hershberger which can be constructed in  $O(n)$  time [4]. Given two points  $p, q \in P$ , this structure allows us to compute the path  $\pi(p, q)$  in  $O(\log n + t)$  time, where  $t$  is the number of vertices in  $\pi(p, q)$ . While constructing these paths using directly will take  $O(n \log n)$  time,

we overcome this issue by splitting the problem into subproblems whose total complexity amounts to  $O(n)$ .

To construct the hourglasses, we start by choosing  $k = n/\log n$  vertices along  $\partial P$ , say  $v_0, v_1, \dots, v_{k-1}$ , chosen by walking along  $\partial P$  in clockwise order and choosing a vertex each time we skip  $\log n$  vertices. That is, there are at most  $\log n$  vertices along  $\partial P$  between  $v_i$  and  $v_{i+1}$  (index taken modulo  $k$ ).

We now compute  $k$  hourglasses, that will have at most  $\log n$  vertices on the top chain. To this end, for each  $0 \leq i \leq k-1$ , we compute the path  $\pi(v_i, f(v_{i+1}))$  and the path  $\pi(v_{i+1}, f(v_i))$ . This two paths together with the chain between  $v_i$  and  $v_{i+1}$  and the chain between  $f(v_{i+1})$  and  $f(v_i)$  form a hourglass. In this way, we obtain  $k = n/\log n$  hourglasses  $H_0, \dots, H_{k-1}$  such that for each  $1 \leq i \leq k-1$ , the top chain of  $H_i$  has at most  $\log n$  vertices. Since  $\sum_{ab \in E} |H_{ab}| = O(n)$  and from the fact that the boundary of each hourglass is contained in the boundary of a hourglass of an edge of  $E$ , we conclude that  $\sum_{i=0}^{k-1} |H_{k-1}| = O(n)$ . Since  $k = n/\log n$ , the  $O(\log n)$  overhead of the shortest-path queries amounts only to  $O(n)$ . Thus, we can compute these  $k$  hourglasses in  $O(n)$  time [4].

We now look at each  $H_i$  independently and recursively split  $H_i$  into smaller hourglasses as follows. Let  $E_i$  be the number of transition edges in the top chain of  $H_i$  and let  $m_i = |H_i|$ . We start by computing the shortest-path data structure for  $H_i$  in  $O(m_i)$  time. Recall that  $|E_i| \leq \log n$  by the way we constructed each  $H_i$ . Note that the hourglass of each transition edge of  $E_i$  is contained in  $H_i$ . Because each of these hourglasses is open, we know that  $\sum_{ab \in E_i} |H_{ab}| = O(m_i)$ .

Two cases arise: if (1)  $|E_i| \leq m_i/\log m_i$ , then computing the  $|E_i|$  hourglasses defined by the transition edges of  $E_i$  takes  $O(|E_i| \log m_i + \sum_{ab \in E_i} |H_{ab}|) = O(m_i)$  time. If we are in this case, then we compute each of the hourglasses and finish the recursion. Otherwise, we know that (2)  $m_i/\log m_i \leq |E_i|$ , and because  $|E_i| \leq \log n$ , we conclude that  $m_i \leq \log^2 n$ . Therefore, by splitting the top chain of  $H_i$  into  $m_i/\log m_i$  chains of length at most  $\log m_i$ , and repeating the process described above, we can construct at most  $m_i/\log m_i$  hourglasses, whose upper chains have at most  $\log m_i = O(\log \log n)$  vertices. Moreover, because the boundary of each of these hourglasses is contained in the boundary of a hourglass of an edge of  $E_i$ , we conclude their total complexity amounts to  $O(m_i)$ . Using the shortest-path data structure of  $H_i$ , we can compute these  $m_i \log m_i$  hourglasses in  $O(m_i)$  time. Since  $\sum_{i=0}^{k-1} m_i = O(n)$ , the total complexity of this step in all hourglasses is at most  $O(n)$ .

Because the length of the top chain of each hourglasses decreases by taking the logarithmic function, after  $O(\log^* n)$  rounds we will be able to compute all the hourglasses for the edges of  $E$ . We obtain the following result.

► **Lemma 7.** *If  $E$  is the set of transition edges of  $P$ , then we can construct the hourglass of each edge  $E$  in total  $O(n \log^* n)$  time.*

## 5 Covering the polygon with apexed triangles

An *apexed triangle*  $\triangle = (a, b, c)$  with *apex*  $a$  is triangle contained in  $P$  with an associated distance function  $g_\triangle(x)$ , called the *apex function* of  $\triangle$ , such that (1)  $a$  is a vertex of  $P$ , (2)  $b$  and  $c$  are points on the boundary of  $P$ , and (3) there is a vertex  $w$  of  $P$ , called the *definer* of  $\triangle$ , such that

$$g_\triangle(x) = \begin{cases} -\infty & \text{if } x \notin \triangle \\ |xa| + |\pi(a, w)| = |\pi(x, w)| & \text{if } x \in \triangle \end{cases}$$

In this section, we show how to find a set of  $O(n)$  apexed triangles of  $P$  such that the upper envelope of their apex functions coincides with  $F_P(x)$ . To this end, we first decompose the transition hourglasses into apex triangles that encode all the geodesic distance information inside them. Finally, for each marked vertex  $v \in M$ , we construct a funnel that contains the Voronoi region of  $v$ . We then decompose this funnel into apex triangles that encode the distance from  $v$ .

### 5.1 Inside the hourglass

Let  $ab$  be a transition edge of  $P$  such that  $b$  is the clockwise neighbor of  $a$  along  $\partial P$ . Let  $B_{ab}$  denote the bottom chain of  $H_{ab}$ . As noticed above, a point on  $\partial P$  can be farthest from a vertex in  $B_{ab}$  only if it lies in the open segment  $ab$ . Formally, if  $v$  is a vertex of  $B_{ab}$  such that  $R(v) \neq \emptyset$ , then  $R(v) \cap \partial P \subset ab$ . We claim that not only this Voronoi cell is inside  $H_{ab}$  when restricted to the boundary of  $P$ , but that  $R(v) \subset H_{ab}$ .

► **Lemma 8.** *Let  $v$  be a vertex of  $B_{ab}$ . If  $R(v) \neq \emptyset$ , then  $R(v) \subset H_{ab}$ .*

**Proof.** Because  $R(v) \cap \partial P \subset ab$ , by Lemma 6, we know that  $R(v) \subset S_v(ab)$ . Because  $H_{ab}$  is geodesically convex, we conclude that  $R(v) \subset S_v(ab) \subset H_{ab}$ . ◀

Our objective is to compute  $O(|H_{ab}|)$  apexed triangles that cover  $H_{ab}$ , each with its distance function, such that the upper envelope of these apex functions coincides with  $F_P(x)$  restricted to  $H_{ab}$  where it “matters”.

A similar approach was already carried on by Pollack et al. in [11, Section 3]. They show, given a segment contained in the interior of  $P$ , how to compute a linear number of apexed triangles such that  $F_P(x)$  coincides with the upper envelope of the corresponding apex functions when both are restricted to the given segment.

While the construction we follow is analogous, we use it in the hourglass  $H_{ab}$  instead of the full polygon  $P$ . Therefore, we have to specify what is the relation between the upper envelope of the computed functions and  $F_P(x)$ . We will show that the upper envelope of the apex functions computed in  $H_{ab}$  coincides with  $F_P(x)$  inside the Voronoi cell  $R(v)$  of every vertex  $v \in B_{ab}$ .

Let  $T_a$  and  $T_b$  be the shortest path trees in  $H_{ab}$  from  $a$  and  $b$ , respectively. We can compute these trees in  $O(|H_{ab}|)$  time [3]. For each vertex  $v$  between  $f(a)$  and  $f(b)$ , let  $v_a$  and  $v_b$  be the neighbors of  $v$  in the paths  $\pi(v, a)$  and  $\pi(v, b)$ , respectively. We say that a vertex is *visible* from  $ab$  if  $v_a \neq v_b$ . Note that if a vertex is visible, then the extension of these segments must intersect the top segment  $ab$ . Therefore, for each visible vertex  $v$ , we obtain a triangle  $\Delta_v$  as shown in Figure ??.

We further split  $\Delta_v$  into a series of triangles with apex at  $v$  as follows: Let  $u$  be a children of  $v$  in the tree  $T_a$  rooted at  $a$ . As noted by Pollack et al.,  $v$  can be of three types, either (1)  $u$  is not visible from  $ab$  (and is hence a child of  $v$  in both  $T_a$  and  $T_b$ ); or (2)  $u$  is visible from  $ab$ , is a child of  $v$  only in  $T_b$ , and  $v_bvu$  is a left turn; or (3)  $u$  is visible from  $ab$ , is a child of  $v$  only in  $T_a$ , and  $v_avu$  is a right turn.

Let  $u_1, \dots, u_{k-1}$  be the children of  $v$  of type (2) sorted in clockwise order around  $v$ . Let  $c(v)$  be the maximum distance from  $v$  to any invisible vertex in the subtrees of  $T_a$  and  $T_b$  rooted at  $v$ ; if no such vertex exists, then  $c(v) = 0$ . Define a function  $d_l(v)$  on each vertex  $v$  of  $H_{ab}$  in a recursive fashion as follows: If  $v$  is invisible from  $ab$ , then  $d_l(v) = c(v)$ . Otherwise, let  $d_l(v)$  be the maximum of  $c(v)$  and  $\max\{d_l(u_i) + |u_i v| : u_i \text{ is a child of } v \text{ of type (2)}\}$ . Similarly we define a symmetric function  $d_r(v)$  using the children of type (3) of  $v$ .

For each  $1 \leq i \leq k-1$ , extend the segment  $u_i v$  past  $v$  until it intersects  $ab$  at a point  $s_i$ . Let  $s_0$  and  $s_k$  be the intersections of the extensions of  $vv_a$  and  $vv_b$  with the segment  $ab$ . We define then  $k$  triangles contained in  $\Delta_v$  as follows. For each  $0 \leq i \leq k-1$ , consider the triangle  $\triangle(s_i, v, s_{i+1})$  whose associated apexed (left) function is

$$f_i(x) = |xv| + \max_{j>i} \{c(v), |vu_j| + d_l(u_j)\}.$$

In a symmetric manner, we define a set of apexed triangles induced by the type (3) children of  $v$  and their respective apexed (right) functions.

Let  $g_1, \dots, g_r$  and  $\triangle_1, \dots, \triangle_r$  respectively be an enumeration of all the generated apex functions and triangles such that  $g_i$  is defined in the triangle  $\triangle_i$ . Because each function is determined uniquely by a pair of adjacent vertices in  $T_a$  or in  $T_b$ , and since these trees have  $O(|H_{ab}|)$  vertices, we conclude that  $r = O(|H_{ab}|)$ .

Note that for each  $1 \leq i \leq r$ , the triangle  $\triangle_i$  has two vertices on the segment  $ab$  and a third vertex, say  $a_i$ , called its *apex* such that for each  $x \in \triangle_i$ ,  $g_i(x) = |\pi(x, w_i)|$  for some vertex  $w_i$  of  $H_{ab}$ . We refer to  $w_i$  as the *definer* of  $\triangle_i$ . Intuitively,  $\triangle_i$  defines a portion of the geodesic distance function from  $w_i$  in a constant complexity region.

► **Lemma 9.** *Given a transition edge  $ab$  of  $P$ , we can compute  $O(|H_{ab}|)$  apexed triangles and their respective apex functions in  $O(|H_{ab}|)$  time. Moreover, for any point  $p \in P$  such that  $f(p) \in B_{ab}$ , there is a computed apexed triangle  $\triangle_i$  with apex function  $g_i$  and definer equal to  $f(p)$  such that*

1.  $p \in \triangle_i$  and
2.  $g_i(p) = F_P(p)$ .

**Proof.** Because  $p \in R(f(p))$ , Lemma 8 implies that  $p \in H_{ab}$ . Consider the path  $\pi(p, f(p))$  and let  $v$  be the neighbor of  $p$  along this path. Note that by construction, there is a triangle  $\triangle_i$  apexed at  $v_i$  with definer  $w_i$  that contains  $p$ . Recall that by construction, the apex function  $g_i(x)$  of  $\triangle_i$  encodes the geodesic distance from  $x$  to  $w_i$ . Because  $F_P(x)$  is the upper envelope of all the geodesic functions, we know that  $g_i(p) \leq F_P(p)$ .

To prove the other inequality, note that if  $v_i = f(p)$ , then trivially  $g_i(p) = |pv_i| + |\pi(v_i, w_i)| \geq |pv_i| = |\pi(p, f(p))| = F_P(p)$ . Otherwise, let  $z$  be the next vertex after  $v_i$  in the path  $\pi(p, f(p))$ . Three cases arise:

- (a) If  $z$  is invisible from  $ab$ , then so is  $f(p)$  and hence,

$$|\pi(p, f(p))| = |pv_i| + |\pi(v_i, f(p))| \leq |pv_i| + c(v_i) \leq g_i(p).$$

- (b) If  $z$  is a child of type (2), then  $z$  plays the role of some child  $u_j$  of  $v_i$  in the notation used during the construction. In this case:

$$|\pi(p, f(p))| = |pv_i| + |v_i z| + |\pi(z, f(p))| \leq |pv_i| + |v_i u_j| + d_l(u_j) \leq g_i(p).$$

- (c) If  $z$  is a child of type (3), then an analogous arguments hold using the (right) distance  $d_r$ .

Therefore, regardless of the case  $F_P(p) = |\pi(p, f(p))| \leq g_i(p)$ . ◀

In other words, Lemma 9 says that by considering the apex functions we computed, we do not lose any information inside any region  $R(v)$  of any vertex  $v \in B_{ab}$ .

Following the same intuition, in the next section we construct apexed triangles and their apex functions encoding the distance from the vertices of  $M$ .

## 5.2 Inside the funnels of marked vertices

Recall that for each marked vertex  $v \in M$ , we know at least of one vertex on  $\partial P$  such that  $v$  is its farthest neighbor. Let  $u_1, \dots, u_{k-1}$  be the set of vertices of  $P$  such that  $v = f(u_i)$  and assume that they appear in this order when traversing  $\partial P$  clockwise. Let  $u_0$  and  $u_k$  be the neighbors of  $u_1$  and  $u_{k-1}$  other than  $u_2$  and  $u_{k-2}$ , respectively. Note that both  $u_0u_1$  and  $u_{k-1}u_k$  are transition edges of  $P$ . Thus, we can assume that their transition hourglasses have been computed.

Let  $C_v = (u_0, \dots, u_k)$  and consider the funnel  $S_v(C_v)$ . We call  $C_v$  the *main chain* of  $S_v(C_v)$  while  $\pi(u_k, v)$  and  $\pi(v, u_1)$  are referred to as the *walls* of the funnel. Because  $v = f(u_1) = f(u_{k-1})$ , we know that  $v$  is a vertex of both  $H_{u_0u_1}$  and  $H_{u_{k-1}u_k}$ . Thus, since  $\pi(v, u_1) \subset H_{u_0u_1}$  while  $\pi(v, u_k) \subset H_{u_{k-1}u_k}$ , we can compute both  $\pi(v, u_1)$  and  $\pi(v, u_k)$  in  $O(|H_{u_0u_1}| + |H_{u_{k-1}u_k}|)$  time. Consequently, the funnel  $S_v(C_v)$  can be constructed in  $O(k + |H_{u_0u_1}| + |H_{u_{k-1}u_k}|)$ .

Because a vertex on  $\partial P$  has a unique farthest neighbor by our general position assumption, and since the total sum of the complexities of the transition hourglasses is  $O(n)$  by Lemma 5, we can compute the funnel of each vertex of  $M$  in total  $O(n)$  time.

Since the complexity of the walls of these funnels is bounded by the complexity of the transition hourglasses used to compute them, we get that

$$\sum_{v \in M} |S_v(C_v)| = O\left(n + \sum_{ab \in E} |H_{ab}|\right) = O(n).$$

► **Lemma 10.** *Let  $x$  be a point in  $P$ . If  $v = f(x)$ , then  $x \in S_v(C_v)$ .*

**Proof.** Because  $f(u_0) \neq f(u_k)$ , we know that  $C_v$  is a transition chain. Moreover,  $C_v$  contains  $R(v) \cap \partial P$  by definition. Therefore, by Lemma 6, we know that  $R(v) \subset S_v(C_v)$ . Since  $v = f(x)$ , we know that  $x \in R(v)$  and hence that  $x \in S_v(C_v)$ . ◀

Given a funnel  $S_v(C_v)$ , we would like to split it into  $O(|S_v(C_v)|)$  apexed triangles that encode the distance function from  $v$ . To this end, we compute the shortest path tree  $T_v$  of  $v$  in  $S_v(C_v)$  in  $O(|S_v(C_v)|)$  time [4]. We consider the tree  $T_v$  to be rooted at  $v$  and assume that for each node  $u$  of this tree we have stored the geodesic distance  $|\pi(u, v)|$ .

Let  $w_1$  be the first leaf of  $T_v$  found when walking from  $v$  around  $T_v$  in clockwise order as in an Eulerian tour. Continue this Eulerian tour from  $w_1$  and let  $w_2$  and  $w_3$  be the next two vertices visited. Two cases arise:

**Case 1.** If  $w_1, w_2, w_3$  makes a left turn, then let  $s$  be the first point of the boundary of  $S_v(C_v)$  hit by the ray shooting from  $w_3$  in the direction opposite to  $w_2$  ( $s$  could be equal to  $w_3$  if  $w_3$  already lies on the boundary). We claim that  $s$  and  $w_1$  lie on the same edge of the boundary of  $S_v(C_v)$ . Otherwise, there would be a vertex  $u$  visible from  $w_2$  inside the wedge with apex  $w_2$  spanned by  $w_1$  and  $w_3$ . Note that the first edge of the path  $\pi(u, v)$  is the edge  $uw_2$ . Therefore,  $uw_2$  belongs to the shortest path  $T_v$  contradicting the Eulerian order in which the vertices of this tree are visited as  $u$  should be visited before  $w_3$ . Thus,  $s$  and  $w_1$  lie on the same edge and  $s$  can be computed in  $O(1)$  time. We then construct an apexed triangle  $\triangle(w_1, w_2, s)$  apexed at  $w_2$  with apex function  $g(x) = |xw_2| + |\pi(w_2, v)|$ . We now modify the tree  $T_v$  by removing the edge  $w_1w_2$  and adding the edge  $w_3s$  (no edge is added if  $w_3 = s$ ); see Figure ?? for an illustration.

**Case 2.** If  $w_1, w_2, w_3$  makes a right turn, then let  $s$  be the first point hit by the ray apexed at  $w_2$  that shoots in the direction opposite to  $w_3$ . By the same argument as above, we can show that  $w_1$  and  $s$  lie on the same edge of the boundary of  $S_v(C_v)$ . Therefore, we

can compute  $s$  in  $O(1)$  time. At this point, we construct the apexed triangle  $\Delta(w_1, w_2, s)$  apexed at  $w_2$  with apex function  $g(x) = |xw_2| + |\pi(w_2, v)|$ . We now modify the tree  $T_v$  by removing the edge  $w_1w_2$  and replacing the edge  $w_3w_2$  by the edge  $w_3s$ ; see Figure ??.

► **Lemma 11.** *The above procedure runs in  $O(|S_v(C_v)|)$  time and computes  $O(|S_v(C_v)|)$  interior disjoint apexed triangles such that their union covers  $S_v(C_v)$ . Moreover, for each point  $x \in S_v(C_v)$ , there is an apexed triangle  $\Delta$  with apex function  $g(x)$  such that (1)  $x \in \Delta$  and (2)  $g(x) = |\pi(x, v)|$ .*

**Proof.** The above procedure splits  $S_v(C_v)$  into apexed triangles, such that the apex function in each of them is defined as the geodesic distance to  $v$ . Since the path towards  $v$  of every point in these triangles has to go through their apex, we obtain properties (1) and (2).

To bound the running time and complexity we proceed as follows. We can compute the shortest-path tree  $T_v$  from  $v$  in  $O(|S_v(C_v)|)$  time [4]. Note that processing either Case 1 or 2 of the algorithm takes constant time. Therefore, we are only interested in the number of times these steps are performed. Note that we are removing a leaf of the tree in each iteration. In Case 2, the number of leaves strictly decreases, while in case one a new leaf is added if  $s \neq w_3$ . However, the number of leaves that can be added is at most the number of edges of  $T_v$ . Note that the edges added by either Case 1 or 2 are chords of the polygon and hence cannot generate further leaves. Because  $|T_v| = O(|S_v(C_v)|)$ , we conclude that either Case 1 or 2 is only executed  $O(|S_v(C_v)|)$  times yielding the bound in the number of produced apexed triangles and in the running time. ◀

## 6 Prune and search

In this section, we describe a procedure that finds either the geodesic center of  $P$ , or a convex trapezoid that contains the geodesic center. The idea of the proof is to consider the chords of the apexed triangles computed in previous sections and use a cutting of them that splits  $P$  into  $O(1)$  cells. Then, we test on which cell the geodesic center lies and recurse on that cell as a new subproblem having smaller complexity. To decrease the complexity of the problem, we consider only the apexed triangles intersecting this cell in the next iteration. Using the properties of the cutting, we are able to prove that the size of the subproblem decreases by a constant fraction which leads to a linear running time. This algorithm has however two stopping conditions, one is to reach a subproblem of constant size, and a second one is to find a convex trapezoid containing the geodesic center. In the latter case, we are not able to proceed with the prune and search. Nevertheless, by restricting the search space to a convex object, we are able to perform standard optimization techniques to find the geodesic center.

Let  $\tau$  be the set all apexed triangles computed in previous sections.

► **Lemma 12.** *Each point of  $P$  is in at least one apexed triangle of  $\tau$ . Moreover  $|\tau| = O(n)$ .*

**Proof.** Let  $x$  be a point in  $P$ . If  $f(x)$  is a marked vertex, then by Lemma 10 we know that  $x \in S_{f(x)}(C_{f(x)})$ . Moreover, by Lemma 11, we know that there is an apexed triangle that cover  $x$ . Otherwise, if  $f(x)$  is not marked, then it belongs to the lower chain of some transition hourglass. Therefore, by Lemma 9 there is a triangle covering it.

To bound the complexity of  $\tau$ , recall that  $E$  denotes the set of transition edges of  $P$ . Because  $\sum_{ab \in E} H_{ab} = O(n)$  by Lemma 5 and since there are  $O(|H_{ab}|)$  apexed triangles in each transition hourglass  $H_{ab}$ , we conclude that there  $O(n)$  apexed triangles constructed using Lemma 5.

Furthermore, we know that  $\sum_{v \in M} |S_v(C_v)| = O(n)$ . Because each funnel  $S_v(C_v)$  is subdivided into  $O(|S_v(C_v)|)$  apexed triangles by Lemma 11, we conclude that at most

$O(n)$  apexed triangles are constructed inside funnels of marked vertices. Consequently  $|\tau| = O(n)$ .  $\blacktriangleleft$

A *P-chain* is a polygonal chain contained in the boundary of  $P$ . A *P-cell* is a simple polygon contained in  $P$  bounded by a *P-chain* and a polygonal chain of length at most four contained in the interior of  $P$  that connects the endpoints of this *P-chain*. Moreover, a *P-cell* contains the geodesic center of  $P$ . The recursive algorithm described in this section takes as input a *P-cell* (originally the whole polygon  $P$ ) and the set of apexed triangles of  $\tau$  that intersect this *P-cell*, and produces then a new *P-cell* of smaller complexity.

Given a *P-cell*  $R$ , let  $\tau_R$  be the set of apexed triangles of  $\tau$  that intersect  $R$ . Let  $R$  be a *P-cell* and assume that the set  $\tau_R$  has been computed. Let  $m = \max\{|R|, |\tau_R|\}$ .

Note that each triangle of  $\tau_R$  consists of at least one chord of  $R$ . Let  $C$  be the set containing all chords that bound a triangle of  $\tau_R$ . A *half-chord* of  $R$  is either of the simple polygons in which a chord of  $R$  splits this polygon. An *R-trapezoid* is the simple polygon obtained as the intersection of at most four half-chords. Consider a set  $Q$  of all open *R-trapezoids*. For each  $q \in Q$ , let  $C_q = \{c \in C : c \cap q \neq \emptyset\}$  be the set of chords of  $C$  induced by  $q$ . Finally, let  $Q_C = \{C_q : q \in Q\}$  be the family of subsets of  $C$  induced by  $Q$ .

Consider the range space defined by  $C$  and  $F_C$ . Let  $\varepsilon > 0$ . Because the VC-dimension of this range space is finite, we can compute an  $\varepsilon$ -net  $N$  of  $(C, Q_C)$  of size  $O(\frac{1}{\varepsilon} \log \frac{1}{\varepsilon}) = O(1)$  such that for any *R-trapezoid*  $q$ , if  $q$  intersects no chord of  $N$ , then  $q$  intersects at most  $\varepsilon|C|$  chords of  $C$ . Note that  $N$  can be computed in  $O(n)$  time [8].

Since  $|N| = O(1)$ , we can compute all the intersections in this arrangement in  $O(1)$  time. Moreover, by looking at the endpoints of all the chords in  $N$ , we can implicitly compute the partition of  $R$  into  $O(1)$  sub-polygons that this arrangement induces. While each cell of the arrangement is bounded by a constant number of chords from  $N$  and a connected chain of the boundary of  $R$ , it may not be an *R-trapezoid*. Therefore, we split them into *R-trapezoids* by doing a vertical ray-shooting up and down from every vertex of the arrangement; see Figure ?? . Since only  $O(1)$  ray-shootings are performed, this can be done in additional  $O(m)$  time by walking the boundary of the polygon  $R$ .

We want to decide now which *R-trapezoid* contains the geodesic center of  $P$ . To this end, for each edge of an *R-trapezoid*, we can extend it to a chord  $C$  by doing two ray-shooting queries in  $O(m)$  time. Then, we can use the second part of the relative center algorithm introduced by Pollack et al. [11, Section 3] to find the point on  $C$  that minimizes  $F_P(x)$  (during the first part of their algorithm they compute the equivalent of apex functions restricted to  $C$ ). This algorithm is an extension of the linear programming technique introduced by Megiddo [9]. The only requirement of this technique is that the function  $F_P(x)$  coincides with the upper envelope of the apex functions when restricted to  $C$ .

Recall that  $\tau_R$  consists of all the apexed triangles that intersect  $R$ . Thus, we have all the apexed triangles that intersect  $C$ . Consequently, Lemmas 9 and 11 imply that the upper envelope of the apex functions coincides with  $F_P(x)$  when restricted to  $C$ . Let  $p \in C$  be the point that archives the minimum of  $F_P(x)$  (note that  $p$  may be an endpoint of  $C$ ). We want to decide now on which side of  $C$  lies the optimum of  $F_P(x)$ , i.e., the geodesic center of  $x$ . To this end, we consider the apexed triangles whose apex functions define the value of  $F_P(x)$  at  $p$ . They can be found in  $O(m)$  time by looking at all the apexed triangles of  $\tau_R$  that contain  $p$ . We then consider the definers of these apexed triangles. By looking at their distance function to  $p$ , which is encoded by the apex functions, we can decide locally on which side of  $C$  the function decreases and determine the side that contains the optimum of  $F_P(x)$ .

Because the algorithm described by Pollack et al. [11, Section 3] runs in linear time on the number of functions defined on  $C$ , we can decide in total  $O(m)$  time on which side of  $C$

the geodesic center of  $P$  lies.

Because our decomposition into  $R$ -trapezoids has constant complexity, we need to perform this test only  $O(1)$  times before determining the  $R$ -trapezoid  $q^*$  that contains the geodesic center of  $P$ . Since  $N$  is a  $\varepsilon$ -net, we know that at most  $\varepsilon|C|$  chords of  $C$  intersect  $q^*$ .

If  $q^*$  is contained in the interior of  $R$ , then  $q^*$  is convex. In this case, we have found a convex trapezoid that contains the solution and this algorithm finishes. Otherwise,  $q^*$  is a  $P$ -cell bounded by at most three segments, say  $\alpha, \beta$  and  $\gamma$ , and some  $P$ -chain  $R_{q^*}$ ; see Figure ???. In order to proceed with the algorithm on  $q^*$  recursively, we need to compute the set  $\tau_{q^*}$  of at most  $\varepsilon|C|$  apexed triangles of  $\tau_R$  that intersect  $q^*$ . We proceed as follows.

For each apexed triangle  $\triangle \in \tau_R$ , we consider the index of its endpoints and test in  $O(1)$  time if any of them lies on the  $P$ -chain  $R_{q^*}$ . If they do, then they intersect  $q^*$ . Otherwise, we know that this triangle has no endpoint in  $R_{q^*}$  and could only intersect  $q^*$  if one of its edges intersects either  $\alpha, \beta$  or  $\gamma$ . Since this can be tested in  $O(1)$  time, we conclude that the at most  $\varepsilon|C|$  triangles of  $\tau_R$  that intersect  $q^*$  can be found in  $O(m)$  time. Because  $|C| \leq 2m$ , we guarantee that at most  $2\varepsilon m$  apexed triangles intersect  $q^*$ . Moreover, because each vertex of  $q^*$  is in at least one apexed triangle of  $\tau_R$  and from the fact that each apexed triangle covers at most three vertices, we conclude that  $q^*$  consists of at most  $6\varepsilon m$ . Thus, by choosing  $\varepsilon = 1/12$ , we guarantee that both the size of the  $P$ -cell  $q^*$  and the number of apexed triangles in  $\tau_{q^*}$  are at most  $m/2$ .

By recursing on  $q^*$ , we guarantee that after  $O(\log m)$  iterations, we will find either a convex trapezoid contained in  $R$  that contains the center, or we reduce the size of  $\tau_R$  to a constant in which case the optimum of  $F_P(x)$  can be found using an exhaustive search in  $O(1)$  time. Since we halve the size of the  $P$ -cell and the number of apexed triangles in each iteration, the total running time of this algorithm is given by the recurrence  $T(m) = T(m/2) + O(m)$  which solves to  $T(m) = O(m)$ . Because  $|\tau| = O(n)$ , the total running time of this algorithm on  $P$  is  $O(n)$ .

► **Lemma 13.** *In  $O(n)$  time we can find either the geodesic center of  $P$  or a convex trapezoid containing this geodesic center.*

## 7 Solving the problem restricted to a convex trapezoid

In the previous section we show how to find either the geodesic center of  $P$ , or a convex trapezoid  $q^*$  contained in  $P$  that contains this center. The important thing to notice is that, as in the case of chords, the upper envelope of the apex functions restricted to  $q^*$  is a convex function, which allow us to do prune and search using cuttings.

Formally, we have  $m = O(n)$  apex triangles  $\tau^* = \{\triangle_1, \triangle_2, \dots, \triangle_m\}$  each with an apex function restricted to this triangle of the form  $g_i(x) = |xa_i| + \kappa_i$ , where  $\kappa_i = |\pi(a_i, w_i)|$  is a constant,  $a_i$  and  $w_i$  are the apex and the definer of  $\triangle_i$ , respectively.

At this point, we claim that our problem can be reduced to the following optimization problem in  $\mathbb{R}^3$ :

(P1). Find a point  $(x, r) \in \mathbb{R}^3$  minimizing  $r$  subject to  $x \in q^*$  and

$$g_i(x) = |xa_i| + \kappa_i \leq r \text{ if } x \in \triangle_{a_i} \text{ for } 1 \leq i \leq m.$$

► **Lemma 14.** *Let  $p \in \mathbb{R}^2$  and  $r \in \mathbb{R}$  such that  $(p, r)$  is the solution to the optimization problem (P1). Then  $p$  is the geodesic center of  $P$ .*

**Proof.** Let  $\phi(x)$  be the upper envelope of the apex functions of every triangle in  $\tau^*$ . We claim that  $\phi(x)$  coincides with the function  $F_P(x)$ . If this claim is true, then the optimum of both functions is the same and hence,  $p$  is the geodesic center of  $P$ .

To prove our claim, let  $y$  be a point in  $P$ , we want to prove that  $\phi(y) = F_P(y)$ . Two cases arise:

**Case 1.** If  $f(y)$  is a marked vertex, then Lemma 10 implies that  $y \in S_{f(y)}(C_{f(y)})$ . Therefore by Lemma 11 there is an apexed triangle  $\Delta$  with apex function  $g(x)$  such that  $y \in \Delta$  and  $g(y) = |\pi(y, f(y))| = F_P(y)$ .

**Case 2.** If  $f(y)$  is not marked, then it belongs to the bottom chain of some transition hourglass. In this case by Lemma 9 there is an apexed triangle  $\Delta$  with apex function  $g(x)$  such that  $y \in \Delta$  and  $g(y) = F_P(y)$ .

Regardless of the case, there is an apexed triangle  $\Delta$  that contains  $y$  such that its apex function  $g(y) = F_P(y)$ . Since each apex function represent the geodesic distance from some vertex of  $P$ , we know that  $\phi(y) \leq F_P(y)$ . Moreover, since  $g(x)$  is an apex function, we know that  $g(y) \leq \phi(y)$ . Because  $g(y) = F_P(y)$  and since  $g(y) \leq \phi(y) \leq F_P(y)$ , we conclude that  $\phi(y) = F_P(y)$  proving our claim.  $\blacktriangleleft$

By Lemma 14, we need only to find the solution to (P1) to find the geodesic center of  $P$ .

This optimization is similar to that studied by Megiddo in [10]. The main difference being that we have apex functions, defined only in their corresponding apexed triangles, instead of functions defined in the entire plane.

We use some observations noted by Megiddo in order to simplify the description of (P1). To simplify the formulas, we square the equations:

$$g_i(x) = \|x\|^2 + 2x \cdot a_i + \|a_i\|^2 = |xa_i|^2 \leq (r - \kappa_i)^2 = r^2 - 2r\kappa_i + \kappa_i^2$$

And finally for each  $1 \leq i \leq m$ , we define the function  $h_i(x, r)$  as follows:

$$h_i(x, r) = \|x\|^2 + 2x \cdot a_i + \|a_i\|^2 - r^2 + 2r\kappa_i - \kappa_i^2 \leq 0$$

Therefore, our optimization problem can be reformulated as:

**(P2).** Find a point  $(x, r) \in \mathbb{R}^3$  such that  $r$  is minimized subject to  $x \in q^*$  and

$$h_i(x, r) \leq 0 \text{ and } r > \max\{\kappa_i\} \text{ (} 1 \leq i \leq m \text{), if } x \in \Delta_{a_i} \text{ for } 1 \leq i \leq m.$$

Although the functions  $h_i(x, r)$  are not linear, they all have the same non-linear terms. Therefore, for  $i \neq j$ , we get that  $h_i(x, r) = h_j(x, r)$  defines a *separating plane*

$$\gamma_{i,j} = \{(x, r) \in \mathbb{R}^3 : 2(a_i - a_j) \cdot x - 2(\kappa_i - \kappa_j)r = \|a_i\|^2 - \|a_j\|^2 - \kappa_i^2 + \kappa_j^2\}$$

As noted by Megiddo, this separating plane has the following property: If the solution  $(x, r)$  to our optimization problem is known to lie to one side of  $\gamma_{i,j}$ , then we know that one of the constraints is redundant.

In Megiddo's problem, it sufficed to have a *side-decision algorithm* to determine on which side of a plane  $\gamma_{i,j}$  the solution lies. Megiddo showed how to implement such an algorithm in linear time on the number of constraints [10].

Using this side-decision algorithm, he shows how to solve the optimization problem. A variant of his technique could be described as follows: Start by pairing the functions arbitrarily, and then consider the set of separating planes defined by these pairs. Then for some constant  $r$ , compute a  $1/r$ -cutting in  $\mathbb{R}^3$  of the separating planes. A  $1/r$ -cutting is a partition of the plane into  $O(r^2)$  convex cells of constant size such that each intersects at most  $n/r$  separating planes. A cutting of planes can be computed in  $O(n)$  time in  $\mathbb{R}^3$  for any  $r = O(1)$  [7]. After computing the cutting, we determine in which of the cells the optimum lies by performing  $O(1)$  calls to the side-decision algorithm. Because at least  $(r - 1)n/r$

separating planes do not intersect this constant size cell, for each of them we can discard one of the constraints as it becomes redundant. Repeating this algorithm recursively we obtain a linear running time.

In this paper, we follow a similar approach, but our set of separating planes needs to be extended in order to handle apex functions as they are only partially defined. Note that each apexed triangle that intersects  $q^*$  has its endpoints either outside of  $q^*$  or on its boundary, i.e., each chord bounding an apexed triangle splits  $q^*$  into two convex regions.

## 7.1 Optimization problem in a convex domain

In this section we describe our algorithm to solve the optimization problem (P2). To this end, we start by pairing the apexed triangles arbitrarily to obtain  $m/2$  pairs. By identifying the plane where  $P$  lies with the plane  $Z_0 = \{(x, y, z) : z = 0\}$ , we can embed each apexed triangle in  $\mathbb{R}^3$ . A *plane-set* is a set consisting of at most five planes in  $\mathbb{R}^3$ . For each pair  $(\Delta_i, \Delta_j)$  we define a plane-set as follows: For each chord bounding either  $\Delta_i$  or  $\Delta_j$ , consider the line extending this chord and the vertical extrusion of this line in  $\mathbb{R}^3$ , i.e., the plane containing this chord orthogonal to  $Z_0$ . Moreover, consider the separating plane  $\gamma_{i,j}$ . The set containing these planes is the plane-set of the pair  $(\Delta_i, \Delta_j)$ .

Let  $\Gamma$  be the union of all the plane-sets defined by the  $m/2$  pairs of apexed triangles. Thus,  $\Gamma$  is a set that consists of  $O(m)$  planes. Compute an  $1/r$ -cutting of  $\Gamma$  in  $O(m)$  time for some constant  $r$  to be specified later. Because  $r$  is constant, this  $1/r$ -cutting splits the space into  $O(1)$  convex cells, each bounded by a constant number of planes [7]. By using a side-decision algorithm (to be specified later), we can determine the cell  $Q$  of the cutting that contains the solution. Because  $Q$  is the cell of a  $1/r$ -cutting of  $\Gamma$ , we know that at most  $|\Gamma|/r$  planes of  $\Gamma$  intersect  $Q$ . In particular, at most  $|\Gamma|/r$  plane-sets intersect  $Q$  and hence, at least  $(r-1)|\Gamma|/r$  plane-sets do not intersect  $Q$ .

Let  $(\Delta_i, \Delta_j)$  be a pair such that its plane-set does not intersect  $Q$ . Let  $Q'$  be the projection of  $Q$  on the plane  $Z_0$ . Because the plane-set of this pair does not intersect  $Q$ , we know that  $Q'$  intersects neither the boundary of  $\Delta_i$  nor that of  $\Delta_j$ . Two cases arise:

**Case 1.** If either  $\Delta_i$  or  $\Delta_j$  does not intersect  $Q'$ , then we know that their apex function is redundant and we can drop the constraint associated with this apexed triangle.

**Case 2.** If  $Q' \subset \Delta_i \cap \Delta_j$ , then we need to decide which constrain to drop. To this end, we consider the separating plane  $\gamma_{i,j}$ . Notice that inside the vertical extrusion of  $\Delta_i \cap \Delta_j$  (and hence in  $Q$ ), the plane  $\gamma_{i,j}$  has the property that if we know its side containing the solution, then one of the constraints can be dropped. Since  $\gamma_{i,j}$  does not intersect  $Q$  as  $\gamma_{i,j}$  belongs to the plane-set of  $(\Delta_i, \Delta_j)$ , we can decide which side of  $\gamma_{i,j}$  contains the optimum and drop one of the constraints.

Regardless of the case if the plane-set of a pair  $(\Delta_i, \Delta_j)$  does not intersect  $Q$ , then we can drop one of its constraints. Since at least  $(r-1)|\Gamma|/r$  plane-sets do not intersect  $Q$ , we can drop at least  $(r-1)|\Gamma|/r$  constraints. Because  $|\Gamma| \geq m/2$  as each plane-set contains at least one plane, by choosing  $r = 2$ , we are able to drop at least  $|\Gamma|/2 \geq m/4$  constraints. Consequently, after  $O(m)$  time, we are able to drop  $m/4$  apexed triangles. By repeating this process recursively, we end up with a constant size problem in which we can compute the upper envelope of the functions explicitly and find the minimum using exhaustive search. Thus, the running time of this algorithm is bounded by the recurrence  $T(m) = T(3m/4) + O(m)$  which solves to  $O(m)$ . Because  $m = O(n)$ , we obtain the following result.

► **Theorem 15.** *Let  $q^*$  be a convex trapezoid contained in  $P$  such that  $q^*$  contains the*

geodesic center of  $P$ . Given the set of all apexed triangles of  $\tau$  that intersect  $q^*$ , we can compute the geodesic center of  $P$  in  $O(n)$  time.

► **Corollary 16.** *Given a simple polygon  $P$  with  $n$  vertices, we can compute its geodesic center in  $O(n \log^* n)$ .*
